## Question 1

a)

b)

c)

## Question 2

a)

the relation is reflexive if  $\forall x \in \mathbb{R} ((x, x) \in R)$

subtracting any real number by itself results in zero which is an integer, Hence R is reflexive.

The relation is symmetric if for all  $(x, y) \in R$ ,  $(y, x) \in R$  if  $x \neq y$  we need to show that if  $x - y$  is an integer,  $y - x$  is an integer as well

let  $x - y = k$  where  $x \in \mathbb{Z}$

$y - x = -k$  (arithmetic)

---

$k$  is an integer so  $-k$  is an integer as

hence,  $y - x$  is an integer

Therefore, we have proved that is  $(x, y) \in R$  then  $(y, x) \in R$  and relation  $R$  is symmetric

The relation  $R$  is transitive if for all  $x, y, z \in \mathbb{R}$  if  $xRy$  and  $yRz$  then  $xRz$  holds

so we need to prove that if  $x - y \in \mathbb{Z}$  and  $y - z \in \mathbb{Z}$  then  $x - z \in \mathbb{Z}$

let  $x - y = k_1$  where  $k_1$  is an integer

let  $y - z = k_2$  where  $k_2$  is an integer

$$\begin{aligned}x - z &= (x - y) + (y - z) \text{ (adding and subtracting } y\text{)} \\ &= k_1 + k_2\end{aligned}$$

both  $k_1$  and  $k_2$  are integers so  $k_1 + k_2$  is integer as well, so  $x - z$  is an integer and  $(x, z) \in R$  and the relation  $R$  is transitive

Q.E.D.

b)

i.

the equivalence class of any real number  $x$  is given by

$$[x] = \{y \in \mathbb{R} \mid y - x \in \mathbb{Z}\}$$

let  $y - x$  be an integer  $k$  then  $y = x + k$

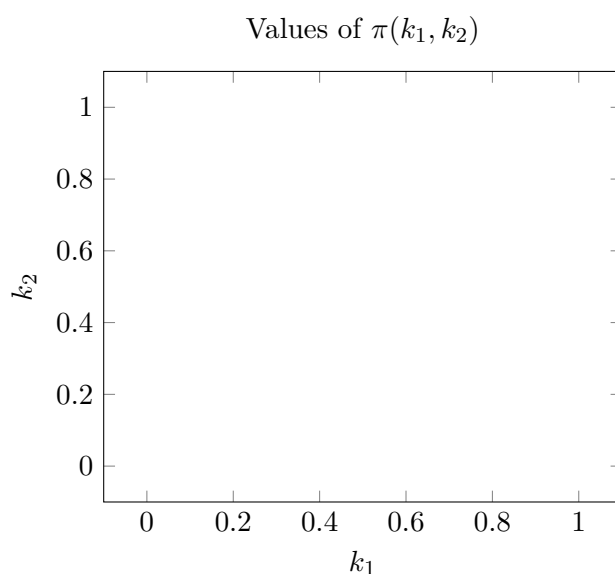

Therefore, the equivalence class of any real number  $x$  consists of all numbers produced by adding an integer to  $x$  since the numbers integers is infinite, each equivalence class is infinite

ii.

as proved in part i every real number has an equivalence classes therefore, the total number of equivalence classes are infinite.

## Question 4

a)

---

b)

The function  $\pi$  is bijection between  $\mathbb{N}^2$  and  $\mathbb{N}$

We need to prove that there exists a bijection between  $\mathbb{N}^n$  and  $\mathbb{N}$

## Question 5

We need to prove that a bijection from  $B$  to  $A^B$  doesn't exist

assume a bijection  $f$  from  $B$  to  $A^B$  exists

for every  $x \in B$ ,  $f(x) \in A^B$ .  $f(x)$  is a function from  $B$  to  $A$ .

Now, we can define new function  $f'$  such that  $f'(x) \neq (f(x))(x)$

since,  $|A| > 2$  we can define this function by choosing a different value from set  $A$  for every value of  $x \in B$

the function  $f$  is a bijection so there must be some value of  $x \in B$  such that  $f(x) = f'$

This contradicts with the definition of  $f'$  function since this would imply that  $f(x)(y) = f'(y)$  for all  $y \in B$

our assumption that  $f$  is a bijection must be false Therefore, a bijection from set  $B$  to  $A^B$  doesn't exist and  $|A^B| \neq |B|$ .

Q.E.D.

## Question 6

a)

**States:**  $Q = \{q_1, q_2, q_3\}$

**Start state:**  $q_0 = q_1$

**Alphabet:**  $\Sigma = \{0, 1\}$

**Accepting states:**  $F = \{q_1, q_3\}$

**State transition:**  $\delta : Q \times \Sigma \rightarrow \mathcal{P}(Q)$

b)

FSM recognises the symbols 1 and 0

- $q_1$  is the starting state and it stays there if it reads 0 and moves to  $q_2$  if it reads 1
- in state  $q_2$  it doesn't move if it reads 0 and moves to  $q_3$  if it reads 1
- in state  $q_3$  it only accepts the symbol 0 and stays in  $q_3$

states  $q_1$  and  $q_3$  are the accepting states

Thus, the FSM accepts strings that contain exactly two 1s and any number of 0s including none anywhere

c)

$0^*10^*10^*$

---

## Question 7

### States:

set of States of the DFSM is the powerset of the states of the original NFSM

$$Q = \{\phi, \{q_0\}, \{q_1\}, \{q_0, q_1\}\}$$

### Initial state:

The initial state of the DFSM is a singleton set containing the initial state of the NFSM  
 $\{q_0\}$  is the initial state

### Accepting states:

accepting states of the DFSM are the states containing any accepting states of NFSM  
 $\{q_1\}$  and  $\{q_0, q_1\}$  are the accepting states

### The Transition Function:

The transition function,  $\delta$ , returns the union of all states that are reachable via the original transition function  $\delta'$ , by consuming the input from any of the NFSM states in the current DFSM state, i.e.,  $\delta(s, x) = \bigcup \{\delta'(q, x) \mid q \in s\}$

The Result could be simplified by removing the state  $\{q_1\}$  since there is no way to reach the state and it's part of the combined state  $\{q_0, q_1\}$

## Question 8

a)

$b^*ab^*aab^*aaab^*$

b)

- $((11)^*1^*)^*$  can be simplified to  $1^*$  since  $(11)^*$  means even number of 1s and the  $1^*$  provides additional 1s which means an empty string of any string made of 1s is accepted
- $(11 + 1)^*$  can be simplified to  $1^*$  because  $11^*$  would be even number of 1s and  $1^*$  would make any number of 1s including none.
- $(0 + \epsilon)^*$  can be simplified to  $0^*$  since  $\epsilon^*$  can be covered by no zeroes included in  $0^*$
- the expression can be further simplified by combining  $1^* + 1^*$  to  $1^*$

final expression is  $1^* + 0^*$
